V.LAVANYA PG Scholar Department of Electrical & Electronics Engineering, Geetanjali institute of Science & Tecnology, Gangavaram;Nellore,nellore (Dt); A.P, India.

Abstract- In recent years, renewable energy sources such as photovoltaic (PV), wind, fuel cell, etc gain importance due to the limitations of conventional energy sources. Renewable energy sources play an important role in rural areas where the power transmission from conventional energy sources is difficult. Other advantages of renewable energy sources are clean, light and does not pollute atmosphere. In order to meet the required load demand, it is better to integrate the renewable energy sources with the load. In this project, a modular interleaved boost converter is first proposed by integrating a forward energy-delivering circuit with a voltage-doubler to achieve high step-up ratio and high efficiency. It is seen that, for higher power applications, more modules can be paralleled to increase the power rating and the dynamic performance of the high step-up converter is proposed for a frontend photovoltaic system. The two-phase configuration not only reduces the current stress through each power switch, but also constrains the input current ripple, which decreases the conduction losses of metal-oxide-semiconductor field effect transistors (MOSFETs). The voltage multiplier module is composed of a conventional boost converter and coupled inductors. An extra conventional boost converter is integrated into the first phase to achieve a considerably higher voltage conversion ratio. The low-voltage-rated MOSFETs can be adopted for reductions of conduction losses and cost. Efficiency improves because the energy stored in leakage inductances is recycled to the output terminal. In this concept the proposed converter output apply to AC loads PV is the input source. These all simulation results are verified by using MATLAB/SIMULINK software.

Index Terms—RES, DC-DC Converter, high step-up converter, photovoltaic (PV), Inverter

## I. INTRODUCTION

Traditionally, Photovoltaic systems (PV) installed around the world are grouped in on-grid and off-grid. The first developed presented greater growth worldwide [1]. They are distinguished by the absence of a storage device, such as battery. One of its main features is the possibility of improving the quality of service of the energy supplied by the electrical-grid. There are three configurations of installation of PV systems that can to be connected to the electrical-grid, are: central inverter, string inverter and multi-string inverter [2], [3], [4], [5], [6], [7]. An improvement that is achieved in PV system consists on the implementation of a PV module with a DC-AC converter small or Module Integrated Converter, MIC, the union of this two is called "AC Module". The AC module easily connects to the electrical-grid under the operate mode of plug and play.

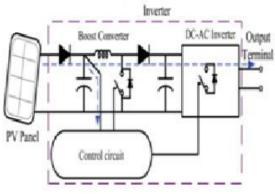

Fig .1: Block diagram of the whole system

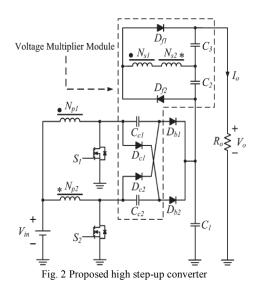

Photovoltaic (PV) power-generation systems are becoming increasingly important and prevalent in distribution and generation systems. An conventional type of PV array is a serial connection of numerous panels to obtain higher dc-link voltage for main electricity through a dc-ac inverter. The total power generated from the PV array is sometimes decreased remarkably when only a few modules are free from shadow effects to overcome this problems several necessary steps are taken. Interactive inverter is individually mounted on PV module and operates so as to generate the maximum power from its corresponding PV module. The inverter includes dc-dc boost converter, dc-ac inverter with control circuit as shown in Fig. 1. The dc-dc converter requires large stepup conversion from the panel's low voltage to the voltage level of the application.

Generally speaking, the high step-up dc–dc converters for these applications have the following common features: 1) High step-up voltage gain. Generally, about a step-up gain is required.2) High efficiency.3) No isolation is required. The proposed converter is a conventional interleaved boost converter integrated with a voltage multiplier module, and the voltage multiplier module is composed of switched capacitors and coupled inductors. The coupled inductors can be designed to extend step-up gain, and the switched capacitors offer extra voltage conversion ratio. In addition, when one of the switches turns off, the energy stored in the magnetizing inductor will transfer via three respective paths; thus, the current distribution not only decreases the conduction losses by lower effective current but also makes currents through some diodes decrease to zero before they turn off, which alleviate diode reverse recovery losses.

There are two major factors related to the efficiency of a high step-up dc–dc converter: large input current and high output voltage. Fig. 1 shows the solar energy through the PV panel and micro inverter to the output terminal when the switches are OFF. When installation of the ac module is taking place, this potential difference could pose hazards to both the worker and the facilities. A floating active switch is designed to isolate the dc current from the PV panel, for when the ac module is off-grid as well as in the non operating condition.

#### **II. OPERATING PRINCIPLES**

The proposed high step-up interleaved converter with a voltage multiplier module is shown in Fig. 2. The voltage multiplier module is composed of two coupled inductors and two switched capacitors and is inserted between a conventional interleaved boost converter to form a modified boost-flyback-forward interleaved structure. When the switches turn off by turn, the phase whose switch is in OFF state performs as a flyback converter, and the other phase whose switch is in ON state performs as a forward converter. Primary windings of the coupled inductors with Np turns are employed to decrease input current ripple, and secondary windings of the coupled inductors with Ns turns are connected in series to extend voltage gain. The turn ratios of the coupled inductors are the same. The coupling references of the inductors are denoted by "." and "\*".

The DC-DC converter requires a large step-up voltage conversion from low voltage obtained from the panel low voltage to the required voltage level for the application. In the previous research on various converters for high stepup applications has included analyses of the switched – capacitor type the voltage-lift type the capacitor-diode voltage multiplier and the boost type integrated with coupled inductor, these converters by increasing turns ratio of coupled inductor obtain higher voltage gain than conventional boost converter. Some converters successfully combined boost and fly back converters, some converters, since various converter combinations are developed to carryout high step up voltage gain by using the coupled-inductor technique. The efficiency and voltage gain of the DC-DC boost converter are constrained by either switches or the reverse recovery issues of the diodes.

At  $t = t_0$ , the power switch S<sub>2</sub> remains in ON state, and the other power switch  $S_1$  begins to turn on. The diodes  $D_{c1}$ , Dc2, Db1, Db2, and Df1 are reversed biased, as shown in figure. The series leakage inductors Ls quickly release the stored energy to the output terminal via flyback-forward diode  $D_{f2}$ , and the current through series leakage inductors  $L_s$  decreases to zero. Thus, the magnetizing inductor  $L_{m1}$ still transfers energy to the secondary side of coupled inductors. The current through leakage inductor  $L_{k1}$ increases linearly, and the other current through leakage inductor *Lk*<sup>2</sup> decreases linearly. At  $t = t_1$ , both of the power switches S1 and S2 remain in ON state, and all diodes are reversed biased, as shown in figure. Both currents through leakage inductors Lk1 and Lk2 are increased linearly due to charging by input voltage source  $V_{in}$ . At  $t = t_2$ , the power switch S<sub>1</sub> remains in ON state, and the other power switch S<sub>2</sub> begins to turn off. The diodes  $D_{c1}$ ,  $D_{b1}$ , and  $D_{f2}$  are reversed biased, as shown in figure. The energy stored in magnetizing inductor Lm2 transfers to the secondary side of coupled inductors, and the other modes of operations are presented in the simulation cases.

#### **III. STEADY-STATE ANALYSIS**

The transient characteristics of circuitry are disregarded to simplify the circuit performance analysis of the proposed converter in CCM, and some formulated assumptions are as follows. 1) All of the components in the proposed converter are ideal. 2) Leakage inductors Lk1, Lk2, and Ls are neglected. 3) Voltages on all capacitors are considered to be constant because of infinitely large capacitance. 4) Due to the completely symmetrical interleaved structure, the related components are defined as the corresponding symbols such as Dc1 and Dc2 defined as Dc.

#### A. Step-Up Gain

The voltage on clamp capacitor Cc can be regarded as an output voltage of the boost converter; thus, voltage Vcc can be derived from

$$V_{Cc} = \frac{1}{1 - D} V_{\rm in} \tag{1}$$

When one of the switches turns off, voltage VC1 can obtain a double output voltage of the boost converter derived from

$$V_{C1} = \frac{1}{1 - D} V_{\rm in} + V_{Cc} = \frac{2}{1 - D} V_{\rm in}$$
<sup>(2)</sup>

The output filter capacitors C2 and C3 are charged by energy transformation from the primary side. When S2 is in ON state and S1 is in OFF state, VC2 is equal to the induced voltage of Ns1 plus the induced voltage of Ns2, and when S1 is in ON state and S2 is in OFF state, VC3 is also equal to the induced voltage of Ns1 plus the induced voltage of Ns2. Thus, voltages VC2 and VC3 can be derived from

$$V_{C2} = V_{C3} = n \cdot V_{\rm in} \left( 1 + \frac{D}{1 - D} \right) = \frac{n}{1 - D} V_{\rm in}$$
(3)

The output voltage can be derived from

$$V_o = V_{C1} + V_{C2} + V_{C3} = \frac{2n+2}{1-D} V_{\rm in}$$
(4)

In addition, the voltage gain of the proposed converter is

$$\frac{V_o}{V_{\rm in}} = \frac{2n+2}{1-D} \tag{5}$$

Equation (5) confirms that the proposed converter has a high step-up voltage gain without an extreme duty cycle. The curve of the voltage gain related to turn ratio n and duty cycle is shown in Fig. 3. When the duty cycle is merely 0.6, the voltage gain reaches ten at a turn ratio n of one; the voltage gain reaches 30 at a turn ratio n of five.

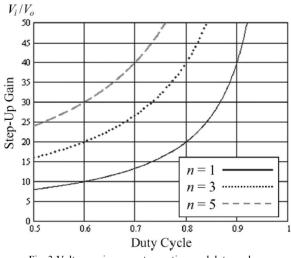

Fig. 3. Voltage gain versus turn ratio n and duty cycle

#### **B.** Voltage Stress on Semiconductor Component

The voltage ripples on the capacitors are ignored to simplify the voltage stress analysis of the components of the proposed converter. The voltage stress on power switch *S* is clamped and derived from

$$V_{S1} = V_{S2} = \frac{2}{1 - D} V_{\text{in}} = \frac{1}{2n + 2} V_o$$
(6)

Equation (6) confirms that low-voltage-rated MOSFET with low RDS(ON) can be adopted for the proposed converter to reduce conduction losses and costs. The voltage stress on the power switch *S* accounts for a fourth of output voltage *Vo*, even if turn ratio *n* is one. This feature makes the proposed converter suitable for high step-up and high-power applications.

The voltage stress on diode Dc is equal to VC1, and the voltage stress on diode Db is voltage VC1 minus voltage VCc. These voltage stresses can be derived from

$$V_{Dc1} = V_{Dc2} = \frac{2}{1 - D} V_{in} = \frac{1}{n + 1} V_o$$
(7)

The voltage stress on diode Db is close to the voltage stress on power switch S. Although the voltage stress on diode Dc is larger, it accounts for only half of output voltage Vo at a turn ratio n of one. The voltage stresses on the diodes are lower as the voltage gain is extended by increasing turn ratio n. The voltage stress on diode Dfequals the VC2 plus VC3, which can be derived from

$$V_{Df1} = V_{Df2} = \frac{2n}{1-D} V_{\rm in} = \frac{n}{n+1} V_o \tag{8}$$

Although the voltage stress on the diode Df increases as the turn ratio n increases, the voltage stress on the diodes Df is always lower than the output voltage.

### IV. PHOTOVOLTAIC (PV) SYSTEM

The power that one module can produce is seldom enough to meet requirements of a home or a business, so the modules are linked together to form an array. Most PV arrays use an inverter to convert the DC power produced by the modules into alternating current that can power lights, motors, and other loads. The modules in a PV array are usually first connected in series to obtain the desired voltage; the individual strings are then connected in parallel to allow the system to produce more current The PV array is made up of number of PV modules connected in series called string and number of such strings connected in parallel to achieve desired voltage and current. The PV module used for simulation study consists of 36 series connected polycrystalline cells. In the crystalline silicon PV module, the complex physics of the PV cell can be represented by the equivalent electrical circuit shown in below figure. For that equivalent circuit, a set of equations have been derived, based on standard theory, which allows the operation of a single solar cell to be simulated using data from manufacturers or field experiments.

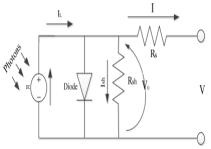

Fig.4 Equivalent electrical circuit of a PV module

The series resistance RS represents the internal losses due to the current flow. Shunt resistance Rsh, in parallel with diode, this corresponds to the leakage current to the ground. The single exponential equation which models a PV cell is extracted from the physics of the PN junction and is widely agreed as echoing the behavior of the PV cell. The number of PV modules connected in parallel and series in PV array are used in expression. The Vt is also defined in terms of the ideality factor of PN junction (n), Boltzmann's constant (KB), temperature of photovoltaic array (T), and the electron charge (q). Applied a dynamical electrical array reconfiguration (EAR)strategy on the photovoltaic (PV) generator of a grid-connected PV system based on a plant-oriented configuration, in order to improve its energy production when the operating conditions of the solar panels are different. The EAR strategy is carried out by inserting a controllable switching matrix between the PV generator and the central inverter, which allows the electrical reconnection of the available PV modules.

## V. SIMULATION RESULTS

Here the simulation carried by two different cases they are 1) high step-up interleaved converter with a voltage multiplier module 2) PV as input source of proposed converter with inverter module

## Case-1 High step-up interleaved converter with a voltage multiplier module

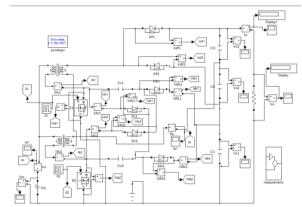

Fig.5 Simulink model of conventional high step-up interleaved converter with a voltage multiplier module

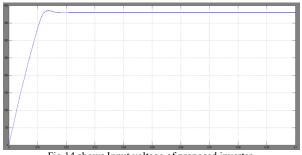

Fig.14 shows Input voltage of proposed inverter

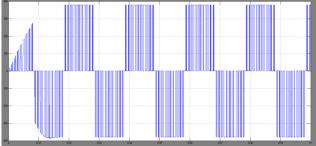

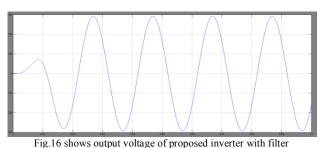

Fig.15 shows output voltage of proposed inverter without filter

VI. CONCLUSION

Renewable energy is the energy generated from natural resources like solar, wind and tidal etc. Solar energy is the radiant light and heat from the sun, which can be converted directly into electrical energy by using photovoltaic effect. As the temperature and isolation changes the output power will change. So in order to achieve more output power from the panel lot of measures should taken, have to reduce the shadow effect etc. We make an analysis for different types of converters with applications in photovoltaic systems, this analysis allow compare quantitatively and qualitatively in source side voltage and load side voltage. The proposed converter has successfully implemented an efficient high step-up conversion through the voltage multiplier module. The interleaved structure reduces the input current ripple and distributes the current through each component. The proposed converter output apply to AC loads PV is the input source. These all simulation results are tested and verified by using MATLAB/SIMULINK software.
